PE05 - Cities with Countries and Currency

Student: Sunidhi Hegde
Course: CS624 - Full-Stack Development: Mobile Applications
Submission: Programming Exercise 05

Project Summary

This programming exercise extends the Cities application by adding country and currency management features. The React Native application uses bottom tab navigation to provide four screens: Cities, Add City, Countries, and Add Country. Users can enter a city and country, view saved cities, select a city, and add location details. The new Add Country screen allows users to enter a country name and its currency. Submitted information is then displayed on the Countries screen. React state is used to store the city and country data during the application session, while reusable components help maintain an organized structure. The application was tested using Expo Web. Testing confirmed that the navigation tabs work correctly, city and country forms accept user input, saved records appear in their lists, and multiple countries can be displayed. The complete source code, configuration files, package information, and project instructions are available in the GitHub repository linked below.
